Ambidexterity Seminar – The Chromatic Picture

Shay Ben Moshe

December 03, 2017

1 Motivation – Hopkins-Neeman and Balmer's Spectrum

Two short introductions to the topic are [7, 9] (note that they use the language of triangular categories, rather than ∞ -categories). In what follows, R is noetherian ring, $X = \operatorname{Spec}(R)$, and $\operatorname{Ch}(X)$ is the symmetric monoidal stable ∞ -category of chain complexes over R.

Problem. Can we recover X from Ch(X)?

The first partial answer to this question is given at [5, 10], later on in [1, 2] the result is further improved, and we will state that version.

Definition 1. A perfect complex is a complex that is quasi-isomorphic to a bounded complex of finite projective modules. These are the compact objects in the category, so that they can actually be defined categorically. Denote by $\operatorname{Ch}_{\operatorname{perf}}(X)$ the full subcategory of perfect complexes.

Definition 2. Let \mathcal{C} be a symmetric monoidal stable ∞ -category. A full subcategory \mathcal{T} is *thick* if:

- 1. $0 \in \mathfrak{T}$
- 2. let $a \xrightarrow{f} b \to c$ cofiber sequence, if two out of $\{a,b,c\}$ are in \mathcal{T} , then so is the third (remember that cofiber and fiber sequences are the same)
- 3. it is closed under retracts

Example 3. Considering the case of $\operatorname{Ch}(X)$ and $\operatorname{Ch}_{\operatorname{perf}}(X)$ (e.g. over \mathbb{Z} , chain complexes of abelian groups, and those with finitely-many non-zero entries, each of which is \mathbb{Z} to some power, respectively). Let $K_{\bullet} \in \operatorname{Ch}(X)$, and define $\mathfrak{T}_{K_{\bullet}} = \{A_{\bullet} \in \operatorname{Ch}_{\operatorname{perf}}(X) \mid A_{\bullet} \otimes K_{\bullet} = 0\}$. Clearly $0 \in \mathfrak{T}_{K_{\bullet}}$. Since tensor is left, it sends pushout to pushout, and three are 0 so the fourth is 0. Lastly, if $A_{\bullet} \to B_{\bullet} \to A_{\bullet}$ is the identity and $B_{\bullet} \otimes K_{\bullet} = 0$ then $\operatorname{id}_{A_{\bullet} \otimes K_{\bullet}}$ factors through 0, thus $A_{\bullet} \otimes K_{\bullet} = 0$. Therefore $\mathfrak{T}_{K_{\bullet}}$ is thick.

Definition 4. A thick subcategory \mathcal{T} is an *ideal* if $a \in \mathcal{T}, b \in \mathcal{C} \implies a \otimes b \in \mathcal{T}$. Furthermore, it is a *prime ideal* if it is a proper subcategory, and $a \otimes b \in \mathcal{T} \implies a \in \mathcal{T}$ or $b \in \mathcal{T}$. The *spectrum* of the category is defined similarly to the classical spectrum of a ring, $\operatorname{Spc}(\mathcal{C}) = \{\mathcal{P} \text{ prime ideal}\}$, and for any family of objects $S \subseteq \mathcal{C}$ we define $V(S) = \{\mathcal{P} \in \operatorname{Spc}(\mathcal{C}) \mid S \cap \mathcal{P} = \emptyset\}$, and these are the closed subsets of the *Zariski topology* on $\operatorname{Spc}(\mathcal{C})$. We also denote $\operatorname{spp}(a) = V(\{a\})$.

Theorem 5 (Balmer). There is a homeomorphism $\varphi: X \to \operatorname{Spc}\left(\operatorname{Ch}_{\operatorname{perf}}\left(X\right)\right)$ given by $\varphi(\mathfrak{p}) = \left\{A_{\bullet} \mid (A_{\bullet})_{\mathfrak{p}} = 0\right\} = \mathfrak{T}_{R_{\mathfrak{p}}}$.

Remark. This was actually upgraded to an isomorphism of locally-ringed spaces.

Proof (sketch). First we note that $\varphi(\mathfrak{p})$ is indeed a prime ideal. It was shown to be thick. It is also clearly an ideal, since $A_{\bullet} \otimes B_{\bullet} \otimes R_{\mathfrak{p}} = A_{\bullet} \otimes 0 = 0$. Finally, if $0 = (A_{\bullet} \otimes B_{\bullet})_{\mathfrak{p}} = (A_{\bullet})_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} (B_{\bullet})_{\mathfrak{p}}$. Assume by negation that $(A_{\bullet})_{\mathfrak{p}} \neq 0$ and $(B_{\bullet})_{\mathfrak{p}} \neq 0$, i.e. $(A_n)_{\mathfrak{p}} \neq 0$ and $(B_m)_{\mathfrak{p}} \neq 0$ but $(A_n)_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} (B_m)_{\mathfrak{p}} = 0$. Well, localization of projective is projective, and a projective over a local ring is free, and clearly if the tensor of two free modules vanish then one of them vanishes, so $(A_n)_{\mathfrak{p}} = 0$ and $(B_m)_{\mathfrak{p}} = 0$ which is a contradiction. Therefore $\varphi(\mathfrak{p})$ is indeed a prime ideal.

Note that

$$\varphi(\mathfrak{p}) \in \operatorname{spp}(A_{\bullet}) \iff A_{\bullet} \notin \varphi(\mathfrak{p}) \iff (A_{\bullet})_{\mathfrak{p}} \neq 0 \iff \mathfrak{p} \in \operatorname{supp}(A_{\bullet})$$

and their complements form bases for the topologies. Thus φ is continous, and if it is invertible, the inverse is continous as well.

Example 6. The case $R = \mathbb{Z}$. Clearly, if $A_{\bullet} \in \mathcal{T}_{\mathbb{Z}_{(p)}}$ then $A_{\bullet} \in \mathcal{T}_{\mathbb{Q}}$, thus any S that doesn't intersect $\mathcal{T}_{\mathbb{Q}}$ doesn't intersect any $\mathcal{T}_{\mathbb{Z}_{(p)}}$, so a closed set that contains $\mathcal{T}_{\mathbb{Q}}$ contains all the others. This is in accordance with the theorem, indeed $p\mathbb{Z} \mapsto \left\{A_{\bullet} \mid (A_{\bullet})_{p\mathbb{Z}} = 0\right\} = \left\{A_{\bullet} \mid A_{\bullet} \otimes \mathbb{Z}_{(p)} = 0\right\} = \mathcal{T}_{\mathbb{Z}_{(p)}}$ and $\mathbb{Z} \mapsto \mathcal{T}_{\mathbb{Z}_{(0)}} = \mathcal{T}_{\mathbb{Q}}$ are prime ideals, and we recovered the toplogy on $\operatorname{Spc}\left(\operatorname{Ch}_{\operatorname{perf}}\left(X\right)\right) = \left\{\mathcal{T}_{\mathbb{Z}_{(2)}}, \mathcal{T}_{\mathbb{Z}_{(3)}}, \ldots, \mathcal{T}_{\mathbb{Q}}\right\}$. Note that the support of an element is all the prime ideals to which it does not belong, e.g. $\mathcal{T}_{\mathbb{Z}_{(q)}} \in \operatorname{spp}\left(\mathbb{F}_p\right)$ iff $\mathbb{F}_p \notin \mathcal{T}_{\mathbb{Z}_{(q)}}$ iff $\mathbb{F}_p \otimes \mathbb{Z}_{(q)} \neq 0$ which is only when q = p, so $\operatorname{spp}\left(\mathbb{F}_p\right) = \left\{\mathcal{T}_{\mathbb{Z}_{(p)}}\right\}$ as we'd expect.

2 The Chromatic Picture

Although the category of spectra doesn't arise as the corresponding category for a scheme or a similar gadget, we can still try to "reconstruct the space X" by applying this mechanism, and then try to use this decomposition.

We will concentrate at the p-local spectra, $\mathrm{Sp}_{(p)}$, for some fixed prime. Such localization is a mild operation, and actually all the statements that follow can be stated at the level of all spectra, but it is easier to state them at $\mathrm{Sp}_{(p)}$. We also remind ourselves that the compact objects are finite spectra.

2.1 Morava K-Theory

A good reference for this part is [8, lectures 22, 24, 25]

Definition 7. Let R be an evenly graded ring. R is called a *graded field* if every non-zero homogenus is invertible, equivalently it is a field F concentrated at degree 0, or $F[\beta^{\pm 1}]$ for β of positive even degree. An A_{∞} -ring spectrum E is a *field* if π_*E is a field.

Proposition 8. A field E has Kunneth, i.e. $E_*(X \otimes Y) \cong E_*(X) \otimes_{\pi_* E} E_*(Y)$ for any spectra X, Y.

Theorem 9 (Definition). For each prime p and n = 1, 2, ..., there exists a spectrum called Morava K-Theory of height n, denoted by K(p, n), which has the following properties:

- $\pi_*K(p,n) \cong \mathbb{F}_p\left[v_n^{\pm 1}\right]$ where $\deg v_n = 2(p^n 1)$.
- It is a field (and in particular, an A_{∞} -ring spectrum).
- If E is a field, then it has the structure of a K(p,n)-module for some p and n. In that sense K(p,n) is uniquely determined.

We also take $K(p,0) = H\mathbb{Q}$.

Example. Remember that K (regular complex K-theory) has $\pi_*K = \mathbb{Z}\left[\beta^{\pm 1}\right]$ where $\deg \beta = 2$. Taking K/p we get a spectrum with homotopy groups $\mathbb{F}_p\left[\beta^{\pm 1}\right]$, and it can be shown that it is a module over K(p,1), and since $\deg v_1 = 2(p-1)$ while $\deg \beta = 2$, K/p is a direct sum of p-1 copies of K(p,1).

2.2 Localization at E

A reference for what follows is at [8, lecture 20]. Let E be a spectrum.

Definition 10. A spectrum Z is called E-acyclic, if $E_*(Z) = \pi_*(E \otimes Z) = 0$ (i.e. $E \otimes Z \simeq 0$). A spectrum Y is called E-local, if $[Z,Y]_* = 0$ (i.e. equivalently Map $(Z,Y) \simeq 0$) for all E-acyclic Z. The E-local spectra form a full subcategory $\operatorname{Sp}_E \subset \operatorname{Sp}$.

Definition 11. Let X be a spectrum, its E-localization is the universal E-local spectrum together with a map $\varphi: X \to L_E X$. I.e. s.t. for each map to an E-local spectrum $f: X \to Y$, there exists a unique $\tilde{f}: L_E X \to Y$ s.t. $f = \tilde{f}\varphi$. In other word, the E-localization is the left adjoint to the inclusion $\operatorname{Sp}_E \subset \operatorname{Sp}$ (and the map corresponds to id $\in \operatorname{Map}(L_E X, L_E X) \cong \operatorname{Map}(X, L_E X)$).

Remark. The name localization might be confusing. We will use this mechanism for K(p,n) which should be though of as a field. Analogously, the \mathbb{F}_p -localization of \mathbb{Z} is \mathbb{Z}_p , i.e. the completion, not the localization (note that we actually want to work in complexes, but this is the result we would get after interpreting $\langle S \mid R \rangle$ as $\mathbb{Z} \langle R \rangle \to \mathbb{Z} \langle S \rangle$).

2.3 The Thick Subcategory Theorem and $\operatorname{Spc}\left(\operatorname{Sp_{(p)}^{fin}}\right)$

Many of the results below can be found at [8, lecture 26]. The Balmer spectrum can be found at [2, corollary 9.5].

Proposition 12. Let $\mathfrak{T}_{E}=\ker E_{*}=\left\{X\in \mathrm{Sp}_{(p)}^{\mathrm{fin}}\mid E_{*}\left(X\right)=0\right\}$ (equivalently $X\otimes E\simeq 0$) i.e. the E-acyclics, then \mathfrak{T}_{E} is thick.

Proof. Clearly $0 \in \mathcal{T}_E$. Let be a cofiber sequence $X \to Y \to Z$, then we get a LES in E_* homology, in which every space is wrapped by the two others, therefore if two are 0, then so is the third:

$$\cdots \rightarrow E_{m-1}(Z) \rightarrow E_m(X) \rightarrow E_m(Y) \rightarrow E_m(Z) \rightarrow E_{m+1}(X) \rightarrow \cdots$$

For a retract $X \to Y \to Y$, we get $E_m(X) \to E_m(Y) \to E_m(X)$, where the middle is 0, and the composition is identity, thus $E_m(X) = 0$.

This leads us to the following definition.

Definition 13. We define $\mathcal{C}_{\geq n} = \mathcal{T}_{K(p,n-1)}$, the K(p,n-1)-acyclics (equivalently $X \otimes K(p,n-1) \simeq 0$). By the above it is thick. Also, $\mathcal{C}_{\geq 0} = \operatorname{Sp}_{(p)}^{\operatorname{fin}}$ and $\mathcal{C}_{\geq \infty} = \{0\}$, which are trivially thick.

Proposition 14. For $X \in \operatorname{Sp_{(p)}^{fin}}$, if $K(p,n)_*(X) = 0$ then $K(p,n-1)_*(X) = 0$.

Remark. This result is not true for any spectrum (e.g. for $H\mathbb{Q}$ whose K(p, n) doesn't vanish at n = 0 but does at n = 1).

Definition 15. We say that a spectrum is of *type* n (possibly ∞), if the first non-zero Morava K-Theory is K(p, n).

Corollary. $\mathcal{C}_{\geq n}$ is the full subcategory of finite p-local spectra of type $\geq n$ (i.e. $\left\{X \in \operatorname{Sp_{(p)}^{fin}} \mid \forall m < n : K\left(p, m\right)_*(X) = 0\right\}$). Thus clearly $\mathcal{C}_{\geq n+1} \subseteq \mathcal{C}_{\geq n}$.

Proposition 16. The inclusion is proper $\mathcal{C}_{\geq n+1} \subsetneq \mathcal{C}_{\geq n}$.

Proposition 17. If $X \in \operatorname{Sp_{(p)}^{fin}}$ is not contractible, then X has finite height. Therefore $\bigcap_{n < \infty} \mathcal{C}_{\geq n} = \{0\} = \mathcal{C}_{\geq \infty}$.

Proof. $X \simeq 0$ iff $H_*(X; \mathbb{Z}) = 0$ iff $H_*(X; \mathbb{F}_p) = 0$. Assume that X is not contractible, then $H_*(X; \mathbb{F}_p)$ is bounded (since X is a finite spectrum), thus for large enough n, by Atiyah-Hirzebruch SS we have $K(p, n)_*(X) \cong H_*(X; \mathbb{F}_p) \left[v_n^{\pm 1}\right]$, i.e. X has finite type. We conclude that $\cap_{n < \infty} \mathcal{C}_{\geq n} = \{0\} = \mathcal{C}_{\geq \infty}$.

Theorem 18 (Thick Subcategory Theorem [6]). If \mathfrak{T} is a thick subcategory of $\operatorname{Sp}^{\text{fin}}_{(p)}$, then $\mathfrak{T} = \mathfrak{C}_{\geq n}$ for some $n = 0, 1, 2, \ldots, \infty$.

Remark. The proof relies on a major theorem called the Nilpotence Theorem.

Proposition 19. $\mathcal{C}_{\geq n}$ is a prime ideal (note that $\mathcal{C}_{\geq 0}$ is not a proper subcategory, thus only for $n = 1, 2, ..., \infty$.)

Proof. For X,Y by Kunneth we have $K(p,n-1)_*(X\otimes Y)=K(p,n-1)_*(X)\otimes K(p,n-1)_*(Y)$. Therefore, if $X\in \mathcal{C}_{\geq n}$, i.e. the homology vanishes, then so does the homology of $X\otimes Y$, i.e. $X\otimes Y\in \mathcal{C}_{\geq n}$, so $\mathcal{C}_{\geq n}$ is an ideal. If $X\otimes Y\in \mathcal{C}_{\geq n}$ then the homology of the product vanishes, therefore one in the right side must vanish (they are graded vector spaces), so $\mathcal{C}_{\geq n}$ is a prime ideal.

Corollary 20. $\operatorname{Spc}\left(\operatorname{Sp_{(p)}^{fin}}\right) = \{\mathfrak{C}_{\geq 1}, \mathfrak{C}_{\geq 2}, \dots, \mathfrak{C}_{\geq \infty}\}$, and the closed subsets are $\{\mathfrak{C}_{\geq k}, \mathfrak{C}_{\geq k+1}, \dots, \mathfrak{C}_{\geq \infty}\}$.

Remark. The chromatic picture can be described for all Sp^{fin} at once, which has all the primes above for each p with the above closed sets, except that all $\mathcal{C}_{>1}$ for different p are the same ($H\mathbb{Q}$ -acyclics.)

2.4 Morava E-Theory

Remark. There are many approaches and flavors to Morava E-Theory. The one we use is based on [3] and [11]. See also [4]. Anoter approach is via deformations of the formal group law of K(p, n), this approach can found at [8].

The results above indicate that K(p,n) "sees" K(p,n-1). (For example, we had the claim that $K(p,n)_*(X)=0 \implies K(p,n-1)_*(X)=0$ for $X\in \operatorname{Sp}_{(p)}^{\operatorname{fin}}$, which implied that any open set containing $\mathfrak{C}_{\geq n+1}$ contained $\mathfrak{C}_{\geq n}$.) The localization $L_{K(p,n)}$ in some sense (which will be more precise later) determines the n-th chromatic level, and an infinitesimal neighbourhood around it, which will allow us to glue. We would like to find a spectrum that sees all $\leq n$ chromatic levels at once.

Remember that \mathbb{S} is analogus to \mathbb{Z} , K(p,n) is analogus to \mathbb{F}_p , so $L_{K(p,n)}$ is analogus to completion at p (localization at \mathbb{F}_p), thus the K(p,n)-local sphere $L_{K(p,n)}\mathbb{S}$ is analogus to $\mathbb{Z}_p = W(\mathbb{F}_p)$, which indeed sees infinitesimal neighbourhood around p.

It makes sense to try an investigate its Galois extensions. I will not give a precise definition, and definitely not for a general Galois Extension, but just to give an idea:

Definition 21 (kind of). Let G be a finite group, and $f:A\to B$ a map between two E_{∞} -ring spectra s.t.:

- 1. f is equivariant w.r.t to the trivial G-action on A,
- 2. $A \to B^{hG}$ is an equivalence,

3. $B \otimes_A B \to \bigoplus_C B, x \otimes y \mapsto (xg,y)$ is an equivalence.

Then B is called a *Galois extension* of A with Galois group G.

Remark. If we think about extension of (clasical) fields, the first condition means that G is acts on B as automorphisms over A, $B^G \subseteq B$ is always a Galois extension, and the second condition ensures that $A = B^G$, the third condition says that G is actually the Galois groups (it might not act faithfully for example).

It turns out that there is a spectrum called *Morava E-Theory*, denoted by E(p,n), which is the maximal Galois extension of $L_{K(p,n)}\mathbb{S}$ (and the Galois group, which is not finite, is called the Morava stabilizer group). It has coefficients $\pi_*E(p,n)\cong W\left(\overline{\mathbb{F}}_p\right)\llbracket u_1,\ldots,u_{n-1}\rrbracket\left[\beta^{\pm 1}\right]$ where $\deg u_i=0,\deg \beta=2$.

The following statement is a formalization of the idea that E(p, n) sees all $\leq n$ chromatic levels at once.

Proposition 22. For $E = K(p, 0) \lor \cdots \lor K(p, n)$ and for E = E(p, n), being *E-acyclic*, being *E-local* and L_E are the same.

Remark. In other words they are Bousfield equivalent, and clearly the first implies the rest.

2.5 Further Results

The ideas above lead to the idea of studying spectra one prime at a time, height-by-height. We would like to know how to work out the original spectrum.

Definition 23. For each n we have a map $L_{E(p,n+1)}X \to L_{E(p,n)}X$, thus we can form the chromatic tower $\ldots \to L_{E(p,2)}X \to L_{E(p,1)}X \to L_{E(p,0)}X$.

Theorem 24 (Chromatic Convergence Theorem [8, lecture 32]). The limit of the chromatic tower is X.

Theorem 25 (Chromatic Square [8, lecture 23]). There is a pullback diagram:

$$\begin{array}{cccc} L_{E(p,n)}X & \longrightarrow & L_{K(p,n)}X \\ & \downarrow & & \downarrow \\ L_{E(p,n-1)}X & \longrightarrow & L_{E(p,n-1)}L_{K(p,n)}X \end{array}$$

The chromatic square gets its name from another relevant theorem (these theorems go under the name fracture theorems):

Theorem 26 (Arithmetic Square). There is a pullback diagram:

$$X \xrightarrow{\hspace*{1cm}} \prod L_{S\mathbb{F}_p} X$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow$$

$$L_{S\mathbb{Q}} X \xrightarrow{\hspace*{1cm}} L_{S\mathbb{Q}} \left(\prod L_{S\mathbb{F}_p} X\right)$$

(where actually $L_{S\mathbb{F}_p}X = L_{S\mathbb{F}_p}X_{(p)}$, so it contains less information then $X_{(p)} = L_{S\mathbb{Z}_{(p)}}X$ is the p-localization and $L_{S\mathbb{F}_p}X$ is the p-completion]).
