December 03, 2017

1 Motivation – Hopkins-Neemar and Balmer's Spectrum

Two short introductions to the topic are [7, 9] (note that they use the language of triangular categories, rather than ∞ -categories). In what follows, R is noetherian ring, $X = \operatorname{Spec}(R)$, and $\operatorname{Ch}(X)$ is the symmetric monoidal stable ∞ -category of chain com-

Problem. Can we recover X from Ch(X)?

plexes over R.

The first partial answer to this question is given at [5, 10], later on in [1, 2] the result is further improved, and we will state that version. **Definition 1.** A perfect complex is a complex that

is quasi-isomorphic to a bounded complex of finite projective modules. These are the compact objects in the category, so that they can actually be defined categorically. Denote by $\operatorname{Ch}_{\operatorname{perf}}(X)$ the full subcategory of perfect complexes.

Definition 2. Let $\mathcal C$ be a symmetric monoidal stable ∞ -category. A full subcategory $\mathcal T$ is thick if:

- 1. $0 \in \mathfrak{T}$
- 2. let $a \stackrel{f}{\to} b \to c$ cofiber sequence, if two out of $\{a,b,c\}$ are in \Im , then so is the third (remember that cofiber and fiber sequences are the same)
- 3. it is closed under retracts

Example 3. Considering the case of $\operatorname{Ch}(X)$ and $\operatorname{Ch}_{\operatorname{perf}}(X)$ (e.g. over \mathbb{Z} , chain complexes of abelian groups, and those with finitely-many non-zero entries, each of which is \mathbb{Z} to some power, respectively.

tively). Let $K_{\bullet} \in \operatorname{Ch}(X)$, and define $\mathfrak{T}_{K_{\bullet}} = \{A_{\bullet} \in \operatorname{Ch}(X)\}$

Clearly $0 \in \mathcal{T}_{K_{\bullet}}$. Since tensor is left, it sends pushout to pushout, and three are 0 so the fourth is 0. Lastly, if $A_{\bullet} \to B_{\bullet} \to A_{\bullet}$ is the identity and $B_{\bullet} \otimes K_{\bullet} = 0$ then $\mathrm{id}_{A_{\bullet} \otimes K_{\bullet}}$ factors through 0, thus $A_{\bullet} \otimes K_{\bullet} = 0$. Therefore $\mathcal{T}_{K_{\bullet}}$ is thick.

Definition 4. A thick subcategory \mathcal{T} is an *ideal* if $a \in \mathcal{T}, b \in \mathcal{C} \implies a \otimes b \in \mathcal{T}$. Furthermore, it is a *prime ideal* if it is a proper subcategory, and $a \otimes b \in \mathcal{T} \implies a \in \mathcal{T}$ or $b \in \mathcal{T}$. The *spectrum* of the category is defined similarly to the classical spectrum of a ring, $\operatorname{Spc}(\mathcal{C}) = \{\mathcal{P} \text{ prime ideal}\}$, and for any family of objects $S \subseteq \mathcal{C}$ we define $V(S) = \mathcal{C} = \mathcal{C}$

 $\{\mathcal{P} \in \operatorname{Spc}(\mathcal{C}) \mid S \cap \mathcal{P} = \emptyset\}$, and these are the closed subsets of the *Zariski topology* on $\operatorname{Spc}(\mathcal{C})$. We also

denote spp $(a) = V(\{a\})$. **Theorem 5** (Balmer). There is a homeomorphism $\varphi: X \to \operatorname{Spc}(\operatorname{Ch}_{\operatorname{perf}}(X))$ given by $\varphi(\mathfrak{p}) = \left\{ A_{\bullet} \mid (A_{\bullet}) \mid \mathfrak{T}_{R_{\mathfrak{p}}} \right\}$.

Remark. This was actually upgraded to an isomorphism of locally-ringed spaces.

Proof (sketch). First we note that $\varphi(\mathfrak{p})$ is indeed a prime ideal. It was shown to be thick. It is also

clearly an ideal, since $A_{\bullet} \otimes B_{\bullet} \otimes R_{\mathfrak{p}} = A_{\bullet} \otimes 0 = 0$. Finally, if $0 = (A_{\bullet} \otimes B_{\bullet})_{\mathfrak{p}} = (A_{\bullet})_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} (B_{\bullet})_{\mathfrak{p}}$. Assume by negation that $(A_{\bullet})_{\mathfrak{p}} \neq 0$ and $(B_{\bullet})_{\mathfrak{p}} \neq 0$, i.e. $(A_n)_{\mathfrak{p}} \neq 0 \text{ and } (B_m)_{\mathfrak{p}} \neq 0 \text{ but } (A_n)_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} (B_m)_{\mathfrak{p}} = 0.$ Well, localization of projective is projective, and a projective over a local ring is free, and clearly if the tensor of two free modules vanish then one of them

vanishes, so $(A_n)_{\mathfrak{p}} = 0$ and $(B_m)_{\mathfrak{p}} = 0$ which is a contradiction. Therefore $\varphi(\mathfrak{p})$ is indeed a prime

ideal. Note that

$$\varphi(\mathfrak{p}) \in \operatorname{spp}(A_{\bullet}) \iff A_{\bullet} \notin \varphi(\mathfrak{p}) \iff (A_{\bullet})_{\mathfrak{p}} \neq 0 \iff$$
 and their complements form bases for the topolo-

gies. Thus φ is continous, and if it is invertible, the

inverse is continous as well.
Example 6. The case
$$R = \mathbb{Z}$$
. Clearly, if $A_{\bullet} \in \mathfrak{I}_{\mathbb{Z}_{(p)}}$ then $A_{\bullet} \in \mathfrak{I}_{\mathbb{Q}}$, thus any S that doesn't in-

Example 6. The case $R = \mathbb{Z}$. Clearly, if $A_{\bullet} \in$ $\mathfrak{I}_{\mathbb{Z}_{(n)}}$ then $A_{\bullet} \in \mathfrak{I}_{\mathbb{O}}$, thus any S that doesn't intersect $\mathcal{T}_{\mathbb{Q}}$ doesn't intersect any $\mathcal{T}_{\mathbb{Z}_{(p)}}$, so a closed set that contains $\mathfrak{T}_{\mathbb{O}}$ contains all the others. This

is in accordance with the theorem, indeed $p\mathbb{Z} \mapsto$ $\left\{ A_{\bullet} \mid (A_{\bullet})_{p\mathbb{Z}} = 0 \right\} = \left\{ A_{\bullet} \mid A_{\bullet} \otimes \mathbb{Z}_{(p)} = 0 \right\} = \mathfrak{T}_{\mathbb{Z}_{(p)}}$

and $\mathbb{Z} \mapsto \mathfrak{T}_{\mathbb{Z}_{(\Omega)}} = \mathfrak{T}_{\mathbb{Q}}$ are prime ideals, and we recovered the toplogy on Spc (Ch_{perf} (X)) = $\{\mathfrak{T}_{\mathbb{Z}_{(2)}}, \mathfrak{T}_{\mathbb{Z}_{(3)}}, \dots$ Note that the support of an element is all the prime ideals to which it *does not* belong, e.g. $\mathfrak{I}_{\mathbb{Z}_{(q)}} \in \operatorname{spp}(\mathbb{F}_p)$ iff $\mathbb{F}_p \notin \mathfrak{I}_{\mathbb{Z}_{(q)}}$ iff $\mathbb{F}_p \otimes \mathbb{Z}_{(q)} \neq 0$ which is only when q = p, so $\operatorname{spp}(\mathbb{F}_p) = \{\mathfrak{I}_{\mathbb{Z}_{(p)}}\}$ as we'd expect.

2 The Chromatic Picture

Although the category of spectra doesn't arise as the corresponding category for a scheme or a similar gadget, we can still try to "reconstruct the space X" by applying this mechanism, and then try to use this decomposition.

We will concentrate at the p-local spectra, $\mathrm{Sp}_{(p)}$, for some fixed prime. Such localization is a mild operation, and actually all the statements that follow can be stated at the level of all spectra, but it is easier to state them at $\mathrm{Sp}_{(p)}$. We also remind ourselves that the compact objects are finite spectra.

2.1 Morava K-Theory

A good reference for this part is [8, lectures 22, 24]

Definition 7. Let R be an evenly graded ring. R is called a graded field if every non-zero homogenus is invertible, equivalently it is a field F concentrated at degree 0, or $F[\beta^{\pm 1}]$ for β of positive even degree. An A_{∞} -ring spectrum E is a field if π_*E is a field. **Proposition 8.** A field E has Kunneth, i.e. $E_*(X \otimes X)$

 $E_*(X) \otimes_{\pi_* E} E_*(Y)$ for any spectra X, Y. **Theorem 9** (Definition). For each prime p and n =

- 1, 2, ..., there exists a spectrum called Morava K-Theory of height n, denoted by K(p,n), which has the following properties:
 - $\pi_*K(p,n) \cong \mathbb{F}_p\left[v_n^{\pm 1}\right]$ where $\deg v_n = 2(p^n-1)$

• It is a field (and in particular, an A_{∞} -ring

spectrum).

• If E is a field, then it has the structure of a K(p,n)-module for unique p and n. In that

sense K(p,n) is uniquely determined. We also take $K(p,0) = H\mathbb{Q}$.

Example. Remember that K (regular complex Ktheory) has $\pi_* K = \mathbb{Z} \left[\beta^{\pm 1} \right]$ where $\deg \beta = 2$. Taking K/p we get a spectrum with homotopy groups $\mathbb{F}_p\left[\beta^{\pm 1}\right]$, and it can be shown that it is a module over K(p,1), and since $\deg v_1=2\,(p-1)$ while $\deg \beta=2,\ K/p$ is a direct sum of p-1 copies of K(p,1).

2.2 Localization at E

A reference for what follows is at [8, lecture 20]. Let E be a spectrum.

Definition 10. A spectrum Z is called E-acyclic, if $E_*(Z) = \pi_*(E \otimes Z) = 0$ (i.e. $E \otimes Z \simeq 0$). A spectrum Y is called E-local, if $[Z,Y]_* = 0$ (i.e. equivalently $\operatorname{Map}(Z,Y) \simeq 0$) for all E-acyclic Z. The E-local spectra form a full subcategory $\operatorname{Sp}_E \subset \operatorname{Sp}$.

Definition 11. Let X be a a spectrum, its E-localization is the universal E-local spectrum together with a map $\varphi: X \to L_E X$. I.e. s.t. for each map to an E-local spectrum $f: X \to Y$, there exists a unique $\tilde{f}: L_E X \to Y$ s.t. $f = \tilde{f} \varphi$. In other word, the E-localization is the left adjoint to the inclusion $\operatorname{Sp}_E \subset \operatorname{Sp}$ (and the map corresponds to id $\in \operatorname{Map}(L_E X, L_E X) \cong \operatorname{Map}(X, L_E X)$).

ing. We will use this mechanism for K(p, n) which should be though of as a field. Analogously, the \mathbb{F}_p -localization of \mathbb{Z} is \mathbb{Z}_p , i.e. the completion, not the localization (note that we actually want to work in complexes, but this is the result we would get after

Remark. The name localization might be confus-

2.3 The Thick Subcategory Theorem and $\operatorname{Spc}\left(\operatorname{Sp_{(n)}^{fin}}\right)$

interpreting $\langle S \mid R \rangle$ as $\mathbb{Z} \langle R \rangle \to \mathbb{Z} \langle S \rangle$).

corollary 9.5].

Many of the results below can be found at [8, lecture 26]. The Balmer spectrum can be found at [2,

Proposition 12. Let $\mathfrak{I}_E = \ker E_* = \left\{ X \in \operatorname{Sp_{(p)}^{fin}} \mid E_* \right.$ (equivalently $X \otimes E \simeq 0$) i.e. the E-acyclics, then \mathfrak{I}_E is thick.

Proof. Clearly $0 \in \mathcal{T}_E$. Let be a cofiber sequence $X \to Y \to Z$, then we get a LES in E_* homology, in which every space is wrapped by the two others,

therefore if two are 0, then so is the third:

$$\cdots \to E_{m-1}(Z) \to E_m(X) \to E_m(Y) \to E_m(Z) \to I$$

For a retract $X \to Y \to Y$, we get $E_m(X) \to$ $E_m(Y) \to E_m(X)$, where the middle is 0, and the composition is identity, thus $E_m(X) = 0$.

This leads us to the following definition. **Definition 13.** We define $\mathcal{C}_{>n} = \mathcal{T}_{K(p,n-1)}$, the K(p, n-1)-acyclics (equivalently $X \otimes K(p, n-1) \simeq$ 0). By the above it is thick. Also, $\mathcal{C}_{\geq 0} = \mathrm{Sp}_{(n)}^{\mathrm{fin}}$ and

 $\mathcal{C}_{>\infty} = \{0\}$, which are trivially thick. **Proposition 14.** For $X \in \operatorname{Sp_{(n)}^{fin}}$, if $K(p,n)_*(X) =$

0 then K(p, n-1), (X) = 0. Remark. This result is not true for any spectrum

(e.g. for $H\mathbb{Q}$ whose K(p,n) doesn't vanish at n=0

but does at n=1). **Definition 15.** We say that a spectrum is of $type \ n$ (possibly ∞), if the first non-zero Morava K-Theory

is K(p,n).

Corollary. $\mathcal{C}_{\geq n}$ is the full subcategory of finite plocal spectra of type $\geq n$ (i.e. $\left\{ X \in \operatorname{Sp_{(p)}^{fin}} \mid \forall m < n : K \right\}$ Thus clearly $\mathcal{C}_{>n+1} \subseteq \mathcal{C}_{>n}$. **Proposition 16.** The inclusion is proper $\mathcal{C}_{>n+1} \subseteq$ $\mathcal{C}_{>n}$.

Proposition 17. If $X \in \mathrm{Sp}^{\mathrm{fin}}_{(p)}$ is not contractible, then X has finite height. Therefore $\cap_{n<\infty} \mathfrak{C}_{\geq n} = \{0\} = \mathfrak{C}_{\geq \infty}$.

Proof. $X \simeq 0$ iff $H_*(X; \mathbb{Z}) = 0$ iff $H_*(X; \mathbb{F}_p) = 0$. Assume that X is not contractible, then $H_*(X; \mathbb{F}_p)$ is bounded (since X is a finite spectrum), thus for large enough n, by Atiyah-Hirzebruch SS we have $K(p,n)_*(X) \cong H_*(X; \mathbb{F}_p)\left[v_n^{\pm 1}\right]$, i.e. X has finite type. We conclude that $\bigcap_{n<\infty} \mathbb{C}_{>n} = \{0\} = \mathbb{C}_{>\infty}$.

 \mathfrak{T} is a thick subcategory of $\mathrm{Sp}_{(p)}^{\mathrm{fin}}$, then $\mathfrak{T}=\mathfrak{C}_{\geq n}$ for some $n=0,1,2,\ldots,\infty$. Remark. The proof relies on a major theorem called

Theorem 18 (Thick Subcategory Theorem [6]). If

the Nilpotence Theorem. **Proposition 19.** $C_{\geq n}$ is a prime ideal (note that

Proposition 19. $\mathfrak{C}_{\geq n}$ is a prime ideal (note that $\mathfrak{C}_{\geq 0}$ is not a proper subcategory, thus only for $n=1,2,\ldots,\infty$.)

Proof. For X, Y by Kunneth we have $K(p, n-1)_*(X)$ $K(p, n-1)_*(X) \otimes K(p, n-1)_*(Y)$. Therefore, if $X \in \mathcal{C}_{>n}$, i.e. the homology vanishes, then so does

the homology of $X \otimes Y$, i.e. $X \otimes Y \in \mathcal{C}_{\geq n}$, so $\mathcal{C}_{\geq n}$ is an ideal. If $X \otimes Y \in \mathcal{C}_{\geq n}$ then the homology of the product vanishes, therefore one in the right side must vanish (they are graded vector spaces), so $\mathcal{C}_{\geq n}$ is a prime ideal. \square

Corollary 20. Spc
$$\left(\operatorname{Sp_{(p)}^{fin}}\right) = \{\mathcal{C}_{\geq 1}, \mathcal{C}_{\geq 2}, \dots, \mathcal{C}_{\geq \infty}\},$$
 and the closed subsets are $\{\mathcal{C}_{\geq k}, \mathcal{C}_{\geq k+1}, \dots, \mathcal{C}_{\geq \infty}\}.$

Remark. The chromatic picture can be described for all $\operatorname{Sp^{fin}}$ at once, which has all the primes above for each p with the above closed sets, except that all $\mathfrak{C}_{\geq 1}$ for different p are the same $(H\mathbb{Q}\text{-acyclics.})$

2.4 Morava E-Theory

Remark. There are many approches and flavors to Morava E-Theory. The one we use is based on [3] and [11]. See also [4]. Anoter approch is via deformations of the formal group law of K(p, n), this approch can found at [8].

The results above indicate that K(p,n) "sees" K(p,n) (For example, we had the claim that $K(p,n)_*(X) = 0 \implies K(p,n-1)_*(X) = 0$ for $X \in \mathrm{Sp}^{\mathrm{fin}}_{(p)}$. And

first the is in the latter's closure.) In some sense (which will be more precise later), K(p,n) determines the n-th chromatic level, and an infinitesimal neighbourhood around it, so that we can glue data from lower height. We would like to find a spectrum that sees all $\leq n$ chromatic levels at once.

Remember that \mathbb{S} is analogus to \mathbb{Z} , and $L_{K(p,n)}$ is analogus to completion at p (localization at \mathbb{F}_p), so the K(p,n)-local sphere $L_{K(p,n)}\mathbb{S}$ is analogus to $\mathbb{Z}_p = W(\mathbb{F}_p)$, and it makes sense to try an investigate its Galois extensions. I will not give a precise definition, and definitely not for a general Galois Extension, but just to give an idea:

Definition 21 (kind of). Let G be a finite group, and $f: A \to B$ a map between two E_{∞} -ring spectra s.t.:

- 1. f is equivariant w.r.t to the trivial G-action on A,
- 2. $A \to B^{hG}$ is an equivalence,
- 3. $B \otimes_A B \to \bigoplus_G B, x \otimes y \mapsto (xg.y)$ is an equivalence.

Then B is called a $Galois\ extension$ of A with Galois group G.

Remark. If we think about extension of (clasical)

fields, the first condition means that G is acts on B as automorphisms over A, $B^G \subseteq B$ is always a Galois extension, and the second condition ensures that $A = B^G$, the third condition says that G is ac-

tually the Galois groups (it might not act faithfully

for example).

It turns out that there is a spectrum called *Morava* E-Theory, denoted by E(p,n), which is the maximal Galois extension of $L_{K(p,n)}\mathbb{S}$ (and the Galois group, which is not finite, is called the Morava stabilizer group). It has coefficients $\pi_*E(p,n) \cong W(\overline{\mathbb{F}}_p)$ $\llbracket u_1, \ldots$

The following statement is a formalization of the idea that $E\left(p,n\right)$ sees all $\leq n$ chromatic levels at once.

where $\deg u_i = 0$ and $\deg \beta = 2$.

Proposition 22. For $E = K(p, 0) \lor \cdots \lor K(p, n)$ and for E = E(p, n), being E-acyclic, being E-local and L_E are the same.

Remark. In other words they are $Bousfield\ equivalent,$ and clearly the first implies the rest.

2.5 Further Results

The ideas above lead to the idea of studying spectra one prime at a time, height-by-height. We would like to know how to work out the original spectrum.

Definition 23. For each n we have a map $L_{E(p,n+1)}X$ $L_{E(p,n)}X$, thus we can form the chromatic tower $\ldots \to L_{E(p,2)}X \to L_{E(p,1)}X \to L_{E(p,0)}X$.

Theorem 24 (Chromatic Convergence Theorem [8, lecture 32]). The limit of the chromatic tower is X.

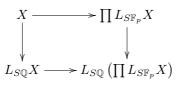

Theorem 25 (Chromatic Square [8, lecture 23]). *There is a pullback diagram:*

$$\begin{array}{cccc} L_{E(p,n)}X & \longrightarrow & L_{K(p,n)}X \\ & & & \downarrow \\ & & \downarrow \\ L_{E(p,n-1)}X & \longrightarrow & L_{E(p,n-1)}L_{K(p,n)}X \end{array}$$

The chromatic square gets its name from another relevant theorem (these theorems go under the name fracture theorems):

Theorem 26 (Arithmetic Square). There is a pull-

back diagram:

(where actually $L_{S\mathbb{F}_p}X = L_{S\mathbb{F}_p}X_{(p)}$, so it contains less information then $X_{(p)}$ [$X_{(p)} = L_{S\mathbb{Z}_{(p)}}X$ is the p-localization and $L_{S\mathbb{F}_p}X$ is the p-completion]).
