Ambidexterity Seminar – The Chromatic Picture

Shay Ben Moshe

December 03, 2017

1 Motivation – Hopkins-Neeman and Balmer's Spectrum

Two short introductions to the topic are [7, 9] (note that they use the language of triangular categories, rather than ∞ -categories). In what follows, R is noetherian ring, $X = \operatorname{Spec}(R)$, and $\operatorname{Ch}(X)$ is the symmetric monoidal stable ∞ -category of chain complexes over R.

Problem. Can we recover X from Ch(X)?

The first partial answer to this question is given at [5, 10], later on in [1, 2] the result is further improved, and we will state that version.

Definition 1. A perfect complex is a complex that is quasi-isomorphic to a bounded complex of finite projective modules. These are the compact objects in the category, so that they can actually be defined categorically. Denote by $\operatorname{Ch}_{\operatorname{perf}}(X)$ the full subcategory of perfect complexes.

Definition 2. Let \mathcal{C} be a symmetric monoidal stable ∞ -category. A full subcategory \mathcal{T} is *thick* if:

- 1. $0 \in \mathfrak{T}$
- 2. let $a \xrightarrow{f} b \to c$ cofiber sequence, if two out of $\{a,b,c\}$ are in \mathcal{T} , then so is the third (remember that cofiber and fiber sequences are the same)
- 3. it is closed under retracts

Example 3. Considering the case of $\operatorname{Ch}(X)$ and $\operatorname{Ch}_{\operatorname{perf}}(X)$ (e.g. over \mathbb{Z} , chain complexes of abelian groups, and those with finitely-many non-zero entries, each of which is \mathbb{Z} to some power, respectively). Let $K_{\bullet} \in \operatorname{Ch}(X)$, and define $\mathfrak{T}_{K_{\bullet}} = \{A_{\bullet} \in \operatorname{Ch}_{\operatorname{perf}}(X) \mid A_{\bullet} \otimes K_{\bullet} = 0\}$. Clearly $0 \in \mathfrak{T}_{K_{\bullet}}$. Since tensor is left, it sends pushout to pushout, and three are 0 so the fourth is 0. Lastly, if $A_{\bullet} \to B_{\bullet} \to A_{\bullet}$ is the identity and $B_{\bullet} \otimes K_{\bullet} = 0$ then $\operatorname{id}_{A_{\bullet} \otimes K_{\bullet}}$ factors through 0, thus $A_{\bullet} \otimes K_{\bullet} = 0$. Therefore $\mathfrak{T}_{K_{\bullet}}$ is thick.

Definition 4. A thick subcategory \mathcal{T} is an *ideal* if $a \in \mathcal{T}, b \in \mathcal{C} \implies a \otimes b \in \mathcal{T}$. Furthermore, it is a *prime ideal* if it is a proper subcategory, and $a \otimes b \in \mathcal{T} \implies a \in \mathcal{T}$ or $b \in \mathcal{T}$. The *spectrum* of the category is defined similarly to the classical spectrum of a ring, $\operatorname{Spc}(\mathcal{C}) = \{\mathcal{P} \text{ prime ideal}\}$, and for any family of objects $S \subseteq \mathcal{C}$ we define $V(S) = \{\mathcal{P} \in \operatorname{Spc}(\mathcal{C}) \mid S \cap \mathcal{P} = \emptyset\}$, and these are the closed subsets of the *Zariski topology* on $\operatorname{Spc}(\mathcal{C})$. We also denote $\operatorname{spp}(a) = V(\{a\})$.

Theorem 5 (Balmer). There is a homeomorphism $\varphi: X \to \operatorname{Spc}\left(\operatorname{Ch}_{\operatorname{perf}}\left(X\right)\right)$ given by $\varphi(\mathfrak{p}) = \left\{A_{\bullet} \mid (A_{\bullet})_{\mathfrak{p}} = 0\right\} = \mathfrak{T}_{R_{\mathfrak{p}}}$.

Remark. This was actually upgraded to an isomorphism of locally-ringed spaces.

Proof (sketch). First we note that $\varphi(\mathfrak{p})$ is indeed a prime ideal. It was shown to be thick. It is also clearly an ideal, since $A_{\bullet} \otimes B_{\bullet} \otimes R_{\mathfrak{p}} = A_{\bullet} \otimes 0 = 0$. Finally, if $0 = (A_{\bullet} \otimes B_{\bullet})_{\mathfrak{p}} = (A_{\bullet})_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} (B_{\bullet})_{\mathfrak{p}}$. Assume by negation that $(A_{\bullet})_{\mathfrak{p}} \neq 0$ and $(B_{\bullet})_{\mathfrak{p}} \neq 0$, i.e. $(A_n)_{\mathfrak{p}} \neq 0$ and $(B_m)_{\mathfrak{p}} \neq 0$ but $(A_n)_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} (B_m)_{\mathfrak{p}} = 0$. Well, localization of projective is projective, and a projective over a local ring is free, and clearly if the tensor of two free modules vanish then one of them vanishes, so $(A_n)_{\mathfrak{p}} = 0$ and $(B_m)_{\mathfrak{p}} = 0$ which is a contradiction. Therefore $\varphi(\mathfrak{p})$ is indeed a prime ideal.

Note that

$$\varphi(\mathfrak{p}) \in \operatorname{spp}(A_{\bullet}) \iff A_{\bullet} \notin \varphi(\mathfrak{p}) \iff (A_{\bullet})_{\mathfrak{p}} \neq 0 \iff \mathfrak{p} \in \operatorname{supp}(A_{\bullet})$$

and their complements form bases for the topologies. Thus φ is continous, and if it is invertible, the inverse is continous as well.

Example 6. The case $R = \mathbb{Z}$. Clearly, if $A_{\bullet} \in \mathcal{T}_{\mathbb{Z}_{(p)}}$ then $A_{\bullet} \in \mathcal{T}_{\mathbb{Q}}$, thus any S that doesn't intersect $\mathcal{T}_{\mathbb{Q}}$ doesn't intersect any $\mathcal{T}_{\mathbb{Z}_{(p)}}$, so a closed set that contains $\mathcal{T}_{\mathbb{Q}}$ contains all the others. This is in accordance with the theorem, indeed $p\mathbb{Z} \mapsto \left\{A_{\bullet} \mid (A_{\bullet})_{p\mathbb{Z}} = 0\right\} = \left\{A_{\bullet} \mid A_{\bullet} \otimes \mathbb{Z}_{(p)} = 0\right\} = \mathcal{T}_{\mathbb{Z}_{(p)}}$ and $\mathbb{Z} \mapsto \mathcal{T}_{\mathbb{Z}_{(0)}} = \mathcal{T}_{\mathbb{Q}}$ are prime ideals, and we recovered the toplogy on $\operatorname{Spc}\left(\operatorname{Ch}_{\operatorname{perf}}\left(X\right)\right) = \left\{\mathcal{T}_{\mathbb{Z}_{(2)}}, \mathcal{T}_{\mathbb{Z}_{(3)}}, \ldots, \mathcal{T}_{\mathbb{Q}}\right\}$. Note that the support of an element is all the prime ideals to which it does not belong, e.g. $\mathcal{T}_{\mathbb{Z}_{(q)}} \in \operatorname{spp}\left(\mathbb{F}_p\right)$ iff $\mathbb{F}_p \notin \mathcal{T}_{\mathbb{Z}_{(q)}}$ iff $\mathbb{F}_p \otimes \mathbb{Z}_{(q)} \neq 0$ which is only when q = p, so $\operatorname{spp}\left(\mathbb{F}_p\right) = \left\{\mathcal{T}_{\mathbb{Z}_{(p)}}\right\}$ as we'd expect.

2 The Chromatic Picture

Although the category of spectra doesn't arise as the corresponding category for a scheme or a similar gadget, we can still try to "reconstruct the space X" by applying this mechanism, and then try to use this decomposition.

We will concentrate at the p-local spectra, $\mathrm{Sp}_{(p)}$, for some fixed prime. Such localization is a mild operation, and actually all the statements that follow can be stated at the level of all spectra, but it is easier to state them at $\mathrm{Sp}_{(p)}$. We also remind ourselves that the compact objects are finite spectra.

2.1 Morava K-Theory

A good reference for this part is [8, lectures 22, 24]

Definition 7. Let R be an evenly graded ring. R is called a *graded field* if every non-zero homogenus is invertible, equivalently it is a field F concentrated at degree 0, or $F[\beta^{\pm 1}]$ for β of positive even degree. An A_{∞} -ring spectrum E is a *field* if π_*E is a field.

Proposition 8. A field E has Kunneth, i.e. $E_*(X \otimes Y) \cong E_*(X) \otimes_{\pi_* E} E_*(Y)$ for any spectra X, Y.

Theorem 9 (Definition). For each prime p and $n = 1, 2, \ldots$, there exists a spectrum called Morava K-Theory of height n, denoted by K(p, n), which has the following properties:

- $\pi_*K(p,n) \cong \mathbb{F}_p\left[v_n^{\pm 1}\right]$ where $\deg v_n = 2(p^n 1)$.
- It is a field (and in particular, an A_{∞} -ring spectrum).
- If E is a field, then it has the structure of a K(p,n)-module for unique p and n. In that sense K(p,n) is uniquely determined.

We also take $K(p,0) = H\mathbb{Q}$.

Example. Remember that K (regular complex K-theory) has $\pi_*K = \mathbb{Z}\left[\beta^{\pm 1}\right]$ where $\deg \beta = 2$. Taking K/p we get a spectrum with homotopy groups $\mathbb{F}_p\left[\beta^{\pm 1}\right]$, and it can be shown that it is a module over K(p,1), and since $\deg v_1 = 2(p-1)$ while $\deg \beta = 2$, K/p is a direct sum of p-1 copies of K(p,1).

2.2 Localization at E

A reference for what follows is at [8, lecture 20]. Let E be a spectrum.

Definition 10. A spectrum Z is called E-acyclic, if $E_*(Z) = \pi_*(E \otimes Z) = 0$ (i.e. $E \otimes Z \simeq 0$). A spectrum Y is called E-local, if $[Z,Y]_* = 0$ (i.e. equivalently Map $(Z,Y) \simeq 0$) for all E-acyclic Z. The E-local spectra form a full subcategory $\operatorname{Sp}_E \subset \operatorname{Sp}$.

Definition 11. Let X be a spectrum, its E-localization is the universal E-local spectrum together with a map $\varphi: X \to L_E X$. I.e. s.t. for each map to an E-local spectrum $f: X \to Y$, there exists a unique $\tilde{f}: L_E X \to Y$ s.t. $f = \tilde{f}\varphi$. In other word, the E-localization is the left adjoint to the inclusion $\operatorname{Sp}_E \subset \operatorname{Sp}$ (and the map corresponds to id $\in \operatorname{Map}(L_E X, L_E X) \cong \operatorname{Map}(X, L_E X)$).

Remark. The name localization might be confusing. We will use this mechanism for K(p,n) which should be though of as a field. Analogously, the \mathbb{F}_p -localization of \mathbb{Z} is \mathbb{Z}_p , i.e. the completion, not the localization (note that we actually want to work in complexes, but this is the result we would get after interpreting $\langle S \mid R \rangle$ as $\mathbb{Z}\langle R \rangle \to \mathbb{Z}\langle S \rangle$).

2.3 The Thick Subcategory Theorem and $\operatorname{Spc}\left(\operatorname{Sp_{(p)}^{fin}}\right)$

Many of the results below can be found at [8, lecture 26]. The Balmer spectrum can be found at [2, corollary 9.5].

Proposition 12. Let $\mathfrak{T}_{E}=\ker E_{*}=\left\{X\in \mathrm{Sp}_{(p)}^{\mathrm{fin}}\mid E_{*}\left(X\right)=0\right\}$ (equivalently $X\otimes E\simeq 0$) i.e. the E-acyclics, then \mathfrak{T}_{E} is thick.

Proof. Clearly $0 \in \mathcal{T}_E$. Let be a cofiber sequence $X \to Y \to Z$, then we get a LES in E_* homology, in which every space is wrapped by the two others, therefore if two are 0, then so is the third:

$$\cdots \rightarrow E_{m-1}(Z) \rightarrow E_m(X) \rightarrow E_m(Y) \rightarrow E_m(Z) \rightarrow E_{m+1}(X) \rightarrow \cdots$$

For a retract $X \to Y \to Y$, we get $E_m(X) \to E_m(Y) \to E_m(X)$, where the middle is 0, and the composition is identity, thus $E_m(X) = 0$.

This leads us to the following definition.

Definition 13. We define $\mathcal{C}_{\geq n} = \mathcal{T}_{K(p,n-1)}$, the K(p,n-1)-acyclics (equivalently $X \otimes K(p,n-1) \simeq 0$). By the above it is thick. Also, $\mathcal{C}_{\geq 0} = \operatorname{Sp}_{(p)}^{\operatorname{fin}}$ and $\mathcal{C}_{\geq \infty} = \{0\}$, which are trivially thick.

Proposition 14. For $X \in \operatorname{Sp_{(p)}^{fin}}$, if $K(p,n)_*(X) = 0$ then $K(p,n-1)_*(X) = 0$.

Remark. This result is not true for any spectrum (e.g. for $H\mathbb{Q}$ whose K(p, n) doesn't vanish at n = 0 but does at n = 1).

Definition 15. We say that a spectrum is of *type* n (possibly ∞), if the first non-zero Morava K-Theory is K(p, n).

Corollary. $\mathcal{C}_{\geq n}$ is the full subcategory of finite p-local spectra of type $\geq n$ (i.e. $\left\{X \in \operatorname{Sp_{(p)}^{fin}} \mid \forall m < n : K\left(p, m\right)_*(X) = 0\right\}$). Thus clearly $\mathcal{C}_{\geq n+1} \subseteq \mathcal{C}_{\geq n}$.

Proposition 16. The inclusion is proper $\mathcal{C}_{\geq n+1} \subsetneq \mathcal{C}_{\geq n}$.

Proposition 17. If $X \in \operatorname{Sp_{(p)}^{fin}}$ is not contractible, then X has finite height. Therefore $\bigcap_{n < \infty} \mathcal{C}_{\geq n} = \{0\} = \mathcal{C}_{\geq \infty}$.

Proof. $X \simeq 0$ iff $H_*(X; \mathbb{Z}) = 0$ iff $H_*(X; \mathbb{F}_p) = 0$. Assume that X is not contractible, then $H_*(X; \mathbb{F}_p)$ is bounded (since X is a finite spectrum), thus for large enough n, by Atiyah-Hirzebruch SS we have $K(p, n)_*(X) \cong H_*(X; \mathbb{F}_p) \left[v_n^{\pm 1}\right]$, i.e. X has finite type. We conclude that $\cap_{n < \infty} \mathcal{C}_{\geq n} = \{0\} = \mathcal{C}_{\geq \infty}$.

Theorem 18 (Thick Subcategory Theorem [6]). If \mathfrak{T} is a thick subcategory of $\operatorname{Sp}^{\text{fin}}_{(p)}$, then $\mathfrak{T} = \mathfrak{C}_{\geq n}$ for some $n = 0, 1, 2, \ldots, \infty$.

Remark. The proof relies on a major theorem called the Nilpotence Theorem.

Proposition 19. $C_{\geq n}$ is a prime ideal (note that $C_{\geq 0}$ is not a proper subcategory, thus only for $n = 1, 2, ..., \infty$.)

Proof. For X, Y by Kunneth we have $K(p, n-1)_*(X \otimes Y) = K(p, n-1)_*(X) \otimes K(p, n-1)_*(Y)$. Therefore, if $X \in \mathcal{C}_{\geq n}$, i.e. the homology vanishes, then so does the homology of $X \otimes Y$, i.e. $X \otimes Y \in \mathcal{C}_{\geq n}$, so $\mathcal{C}_{\geq n}$ is an ideal. If $X \otimes Y \in \mathcal{C}_{\geq n}$ then the homology of the product vanishes, therefore one in the right side must vanish (they are graded vector spaces), so $\mathcal{C}_{\geq n}$ is a prime ideal.

Corollary 20. $\operatorname{Spc}\left(\operatorname{Sp_{(p)}^{fin}}\right) = \{\mathcal{C}_{\geq 1}, \mathcal{C}_{\geq 2}, \dots, \mathcal{C}_{\geq \infty}\}$, and the closed subsets are $\{\mathcal{C}_{\geq k}, \mathcal{C}_{\geq k+1}, \dots, \mathcal{C}_{\geq \infty}\}$.

Remark. The chromatic picture can be described for all $\operatorname{Sp}^{\operatorname{fin}}$ at once, which has all the primes above for each p with the above closed sets, except that all $\mathcal{C}_{>1}$ for different p are the same ($H\mathbb{Q}$ -acyclics.)

2.4 Morava E-Theory

Remark. There are many approches and flavors to Morava E-Theory. The one we use is based on [3] and [11]. See also [4]. Anoter approch is via deformations of the formal group law of K(p, n), this approch can found at [8].

The results above indicate that K(p,n) "sees" K(p,n-1). (For example, we had the claim that $K(p,n)_*(X)=0 \implies K(p,n-1)_*(X)=0$ for $X\in \mathrm{Sp}^{\mathrm{fin}}_{(p)}$. And first the is in the latter's closure.) In some sense (which will be more precise later), K(p,n) determines the n-th chromatic level, and an infinitesimal neighbourhood around it, so that we can glue data from lower height. We would like to find a spectrum that sees all $\leq n$ chromatic levels at once.

Remember that \mathbb{S} is analogus to \mathbb{Z} , and $L_{K(p,n)}$ is analogus to completion at p (localization at \mathbb{F}_p), so the K(p,n)-local sphere $L_{K(p,n)}\mathbb{S}$ is analogus to $\mathbb{Z}_p = W(\mathbb{F}_p)$, and it makes sense to try an investigate its Galois extensions. I will not give a precise definition, and definitely not for a general Galois Extension, but just to give an idea:

Definition 21 (kind of). Let G be a finite group, and $f:A\to B$ a map between two E_{∞} -ring spectra s.t.:

- 1. f is equivariant w.r.t to the trivial G-action on A,
- 2. $A \to B^{hG}$ is an equivalence,
- 3. $B \otimes_A B \to \bigoplus_C B, x \otimes y \mapsto (xg.y)$ is an equivalence.

Then B is called a *Galois extension* of A with Galois group G.

Remark. If we think about extension of (clasical) fields, the first condition means that G is acts on B as automorphisms over A, $B^G \subseteq B$ is always a Galois extension, and the second condition ensures that $A = B^G$, the third condition says that G is actually the Galois groups (it might not act faithfully for example).

It turns out that there is a spectrum called *Morava E-Theory*, denoted by E(p,n), which is the maximal Galois extension of $L_{K(p,n)}\mathbb{S}$ (and the Galois group, which is not finite, is called the Morava stabilizer group). It has coefficients $\pi_*E(p,n)\cong W(\overline{\mathbb{F}}_p)[u_1,\ldots,u_{n-1}][\beta^{\pm 1}]$ where $\deg u_i=0$ and $\deg \beta=2$.

The following statement is a formalization of the idea that $E\left(p,n\right)$ sees all $\leq n$ chromatic levels at once.

Proposition 22. For $E = K(p, 0) \lor \cdots \lor K(p, n)$ and for E = E(p, n), being E-acyclic, being E-local and L_E are the same.

Remark. In other words they are $Bousfield\ equivalent,$ and clearly the first implies the rest.

2.5 Further Results

The ideas above lead to the idea of studying spectra one prime at a time, height-by-height. We would like to know how to work out the original spectrum.

Definition 23. For each n we have a map $L_{E(p,n+1)}X \to L_{E(p,n)}X$, thus we can form the chromatic tower $\ldots \to L_{E(p,2)}X \to L_{E(p,1)}X \to L_{E(p,0)}X$.

Theorem 24 (Chromatic Convergence Theorem [8, lecture 32]). The limit of the chromatic tower is X.

Theorem 25 (Chromatic Square [8, lecture 23]). There is a pullback diagram:

$$\begin{array}{cccc} L_{E(p,n)}X & \longrightarrow & L_{K(p,n)}X \\ \downarrow & & \downarrow \\ L_{E(p,n-1)}X & \longrightarrow & L_{E(p,n-1)}L_{K(p,n)}X \end{array}$$

The chromatic square gets its name from another relevant theorem (these theorems go under the name fracture theorems):

Theorem 26 (Arithmetic Square). There is a pullback diagram:

$$X \longrightarrow \prod L_{S\mathbb{F}_p} X$$

$$\downarrow \qquad \qquad \downarrow$$

$$L_{S\mathbb{Q}} X \longrightarrow L_{S\mathbb{Q}} \left(\prod L_{S\mathbb{F}_p} X \right)$$

(where actually $L_{S\mathbb{F}_p}X = L_{S\mathbb{F}_p}X_{(p)}$, so it contains less information then $X_{(p)} = L_{S\mathbb{Z}_{(p)}}X$ is the p-localization and $L_{S\mathbb{F}_p}X$ is the p-completion]).
